

The science behind the report:

## Partner with Equinix for faster cloud access

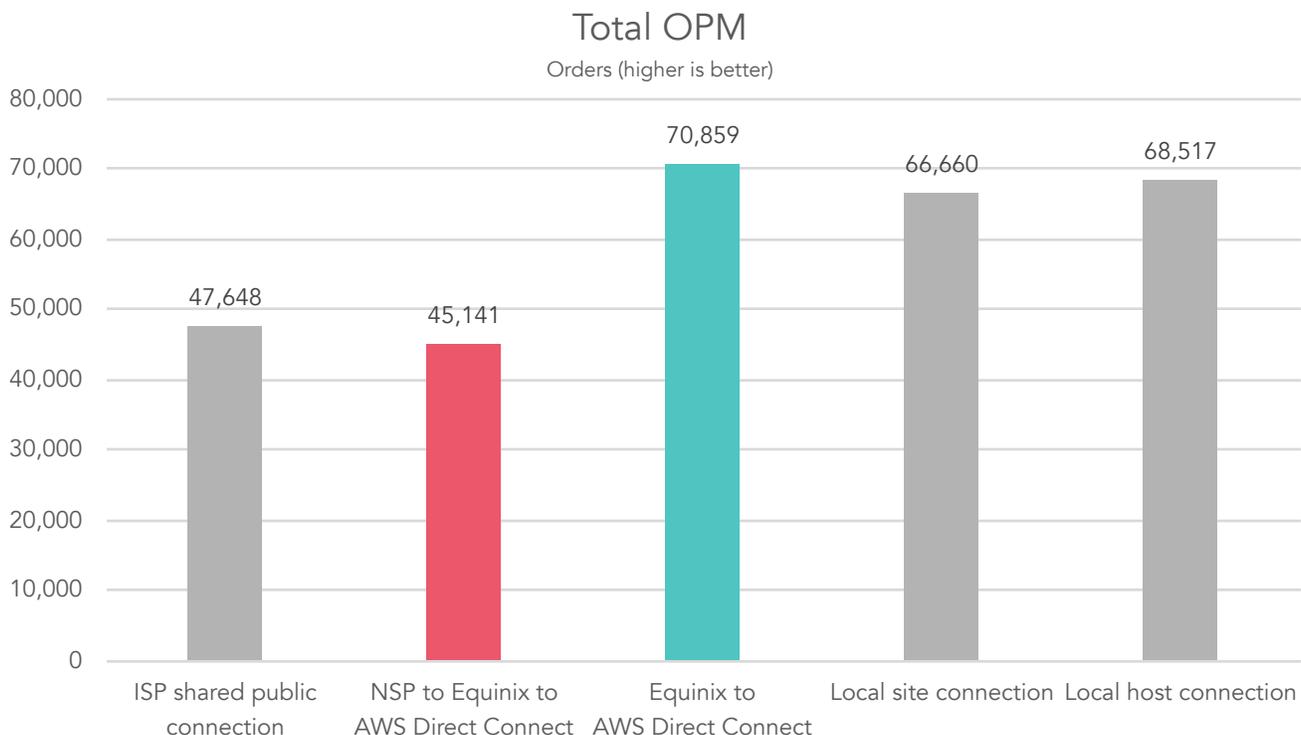

This document describes what we tested, how we tested, and what we found. To learn how these facts translate into real-world benefits, read the report [“Partner with Equinix for faster cloud access”](#).

On March 15, 2018, we finalized the hardware and software configurations we tested. Updates for current and recently released hardware and software appear often, so unavoidably these configurations may not represent the latest versions available when this report appears. For older systems, we chose configurations representative of typical purchases of those systems. Cloud resources reside on shared equipment that is not dedicated to specific workloads. On any given day, variations in resource consumption on shared equipment can produce variability and anomalies in workload performance. We concluded hands-on testing on March 21, 2018.

## Appendix A: Our results

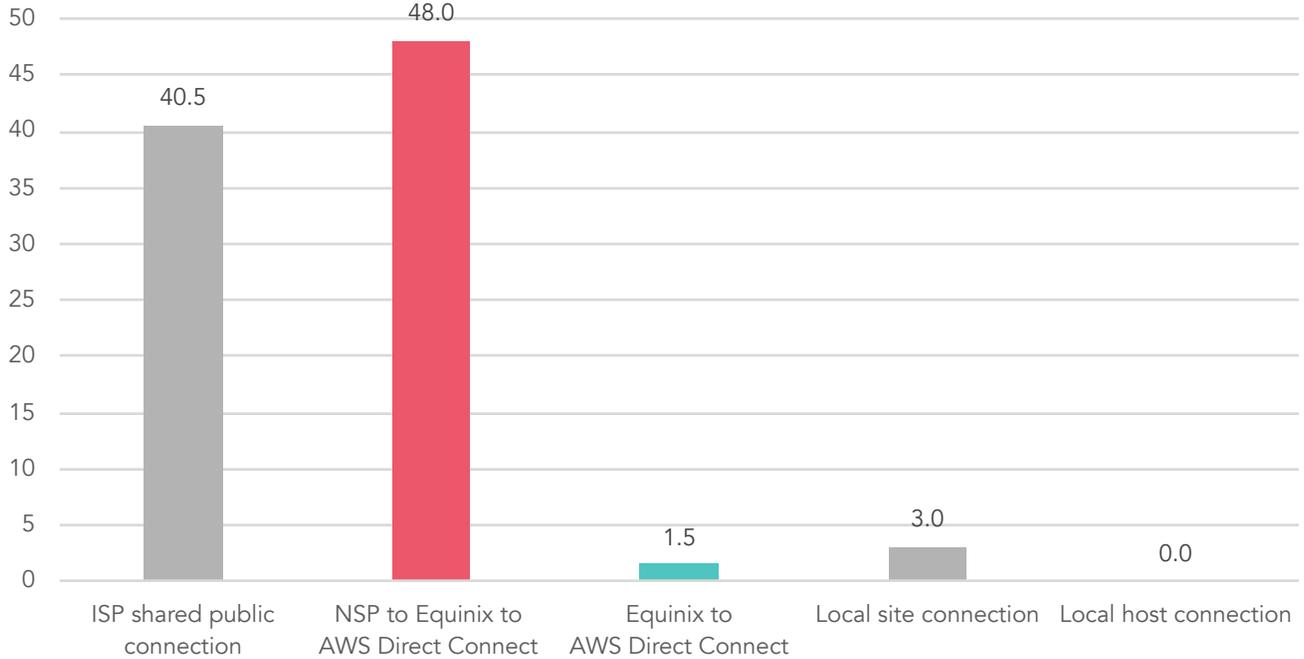

### Results with local comparison

For these tests, we measured both dual-server and single-server connections to determine the amount of latency produced solely by the application. We subtracted the single-server application latency from other test cases to arrive at our average network latency number.

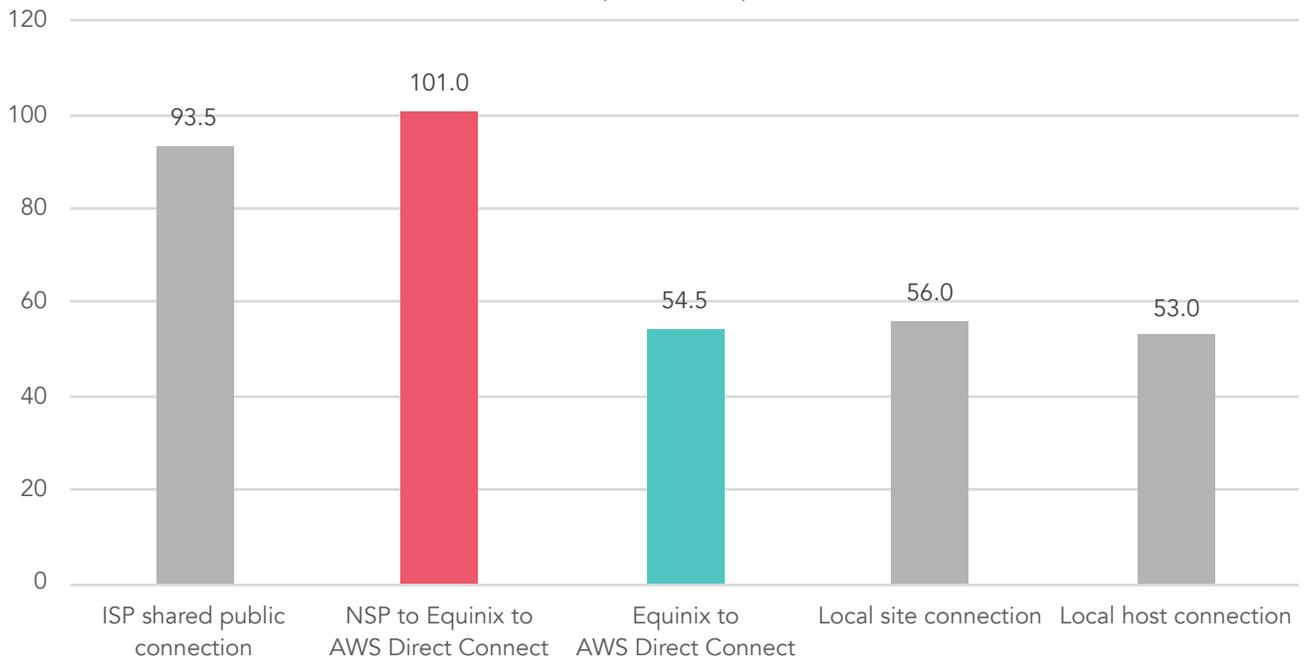

## Average network latency

ms (lower is better)

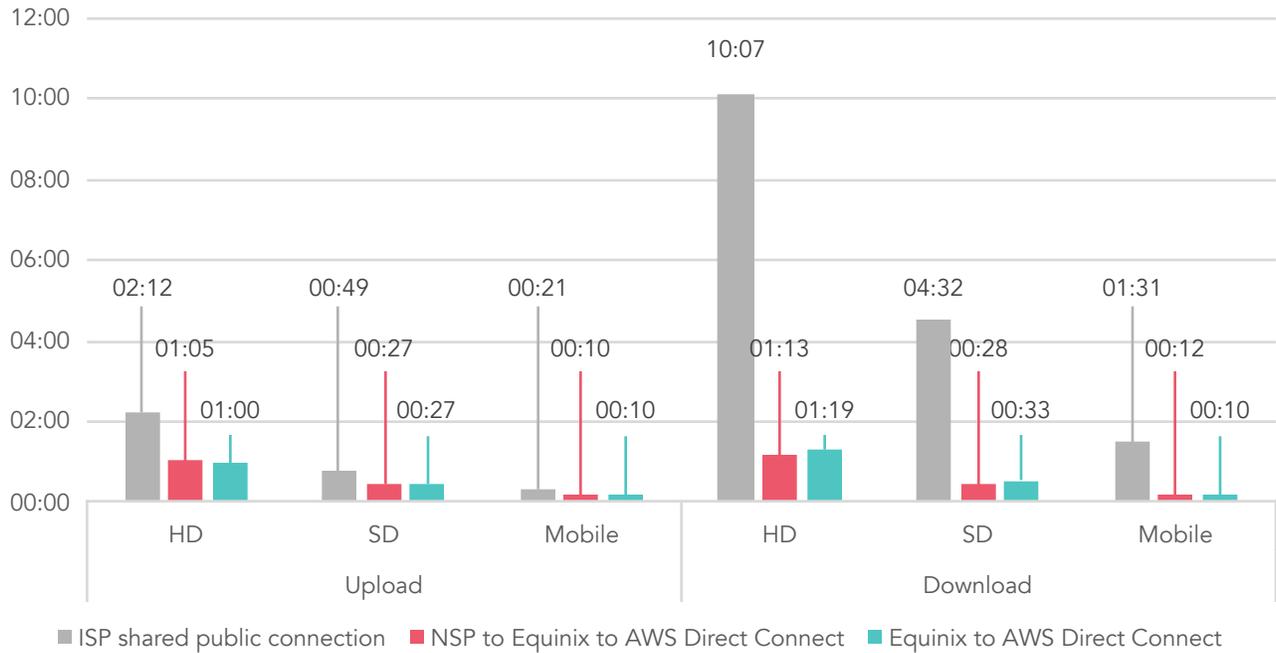

## Average application latency

ms (lower is better)

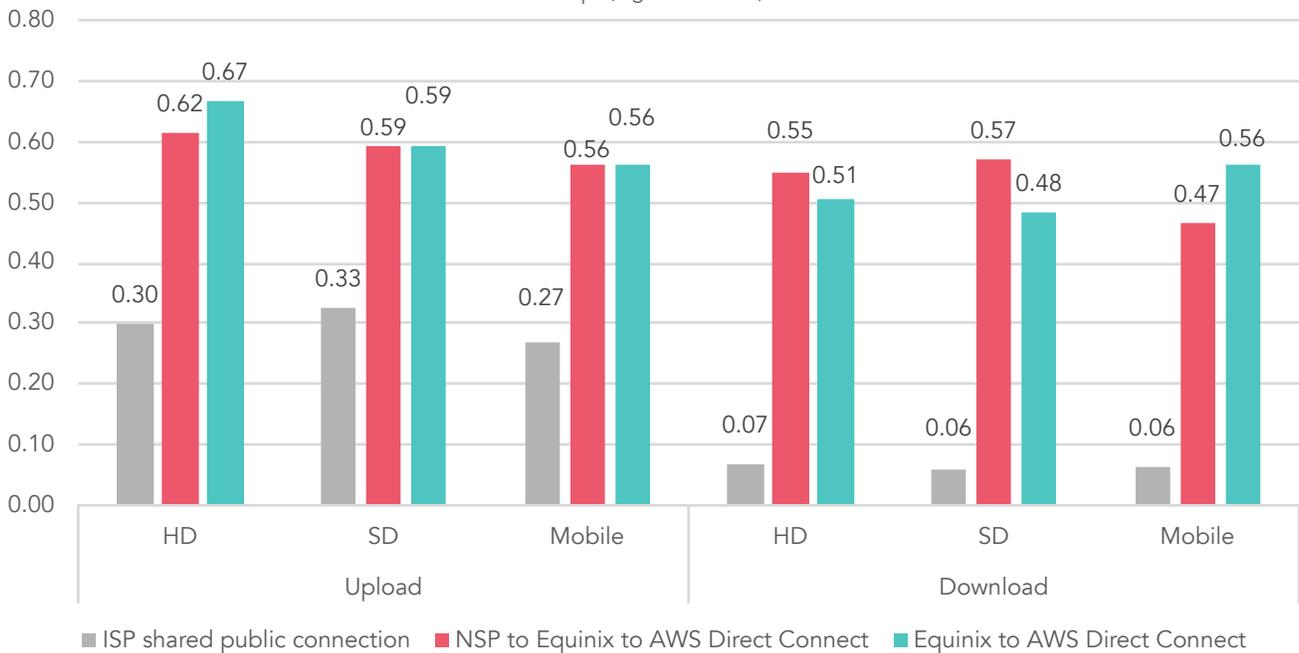

## File transfer times

min:sec (lower is better)

## Throughput

Gbps (higher is better)

## Configuring NetApp FAS3240 and DS4240

### Deploying storage

1. Rack the NetApp disk shelf and controller.
2. Cable the solution appropriately. For more information, see <http://docs.netapp.com/documentation/docweb/index.html?productID=30340&language=en-US>.
3. Power on the disk shelf.
4. Plug a serial console cable into the console port on the top controller in the FAS3240.
5. Plug the other end of the serial console cable into your laptop.
6. Start a terminal emulator (Putty, OS X® Terminal, etc.) on the laptop.
7. Power on the FAS4240.
8. Wait until prompted to escape into the bootloader.
9. On the bootloader prompt, type the following commands:

```
setenv bootarg.init.boot_clustered true
setenv bootarg.factory_init_completed true
setenv bootarg.init.clearvarfsnvram true
```
10. Type: `bye`
11. Click Enter.
12. To start NetApp boot menu, press Control-C.
13. At the boot menu, instead of providing a number, type: `wipeconfig`, and click enter. The system will reboot.
14. At the prompt, to clean configuration and initialize all disks, select 4. The system will reboot again.
15. Perform steps 1 through 14 on the bottom controller in the FAS3240.
16. Follow the initial CLI startup wizards on both controllers.
17. Download and launch the NetApp configuration utility on your laptop. The application will discover the NetApp FAS3240 array and lead you through cluster creation and configuration. The NetApp CLI is now available at the cluster IP address, and the Web UI is available as well.

## Configuring DVD Store 2

For our testing, we generated the data using the Install.pl script included with DVD Store version 2.1 (DS2). This provided the parameters for our 20GB database size and the Microsoft SQL Server 2016 platform. We ran the Install.pl script on a utility system running Linux®. The Install.pl script also generated the database schema.

After processing the data generation, we transferred the data files and schema creation files to a Windows-based system running SQL Server 2016. We built the 4GB database in SQL Server 2016, and then performed a full backup, storing the backup file on the C: drive for quick access. We used that backup file to restore the server between test runs.

The only modification we made to the schema creation scripts were the specified file sizes for our database. We explicitly set the file sizes higher than necessary to ensure that no file-growth activity would affect the outputs of the test. Besides this file size modification, we created and loaded the database schema according to the DVD Store documentation. Specifically, we followed the steps below:

1. We generated the data and created the database and file structure using database creation scripts in the DS2 download. We made size modifications specific to our 20GB database, and the appropriate changes to drive letters.
2. We transferred the files from our Linux data generation system to a Windows system running SQL Server.
3. We created database tables, stored procedures, and objects using the provided DVD Store scripts.
4. We set the database recovery model to bulk-logged to prevent excess logging.
5. We loaded the data we generated into the database. For data loading, we used the import wizard in SQL Server Management Studio. Where necessary, we retained options from the original scripts, such as Enable Identity Insert.
6. Using the database-creation scripts, we created indices, full-text catalogs, primary keys, and foreign keys.
7. We updated statistics on each table according to database-creation scripts, which sample 18 percent of the table data.
8. On the SQL Server instance, we created a ds2user SQL Server login using the following Transact-SQL (T-SQL) script:

```

USE [master]
GO
CREATE LOGIN [ds2user] WITH PASSWORD=N'',
DEFAULT_DATABASE=[master],
DEFAULT_LANGUAGE=[us_english],
CHECK_EXPIRATION=OFF,
CHECK_POLICY=OFF
GO

```

9. We set the database recovery model back to full.
10. Using SQL Server Management Studio, we created the necessary full text index.
11. We created a database user, and mapped this user to the SQL Server login.
12. We performed a full backup of the database. This backup allowed us to restore the databases to a pristine state relatively quickly between tests.

## Configuring the database workload client

For our testing, we used virtual clients for the Microsoft SQL Server client. To create these clients, we installed Windows Server 2016 on Amazon® EC2 instances, assigned a static IP address, and installed .NET 3.5.

## Running the DVD Store tests

For our testing, we created a series of batch files, SQL scripts, and shell scripts to automate the complete test cycle. DVD Store outputs an orders-per-minute (OPM) metric, which is a running average calculated throughout the test. In this report, we document the last OPM reported by each client/target pair, as well as the application latency.

Each complete test cycle consisted of the following general steps:

1. Clean up prior outputs from the target system and the client driver system.
2. Drop the database from the target.
3. Restore the database on the target.
4. Shut down the target.
5. Reboot the host and client system.
6. Wait for a ping response from the server under test and the client system.
7. Let the test server idle for 10 minutes.
8. Start the DVD Store driver on the client.

We used the following DVD Store parameters for testing:

```
ds2sqlserverdriver.exe --target=<target_IP> --ramp_rate=10 --run_time=30 --n_threads=32  
--db_size=20GB --think_time=50 --warmup_time=5 --report_rate=1 --csv_output=<drive path>
```

## Running the file transfer tests

For our testing, we created three different video files to test file transfer times using Windows Explorer. Using a stopwatch, we timed the transfer duration copying to and from the AWS cloud-based VMs with each size of files. For the public internet connection, we tested at different times of day to find a median for performance comparison. We rotated the file tests to ensure that disk caching wasn't reusing the previous copy data.

Running the test cycles:

1. Copy the local source file.
2. To paste while simultaneously starting the timer, select the cloud-based target folder, and type **Ctrl-V**.
3. When the copy finishes, stop the timer.
4. Repeat the process with the next file, until all three have been tested.
5. Reverse the process, copying all three files individually from the cloud folder to a local folder.
6. Delete the local and remote copies of the files.
7. To determine median values, repeat these steps with the original source files a total of three times.
