

SPECjbb2005 performance on Red Hat Enterprise Linux 5.2 Intel-based servers

Executive summary

Red Hat®, Inc. (Red Hat) commissioned Principled Technologies (PT) to measure the SPECjbb®2005 performance of multi-processor servers using the following two processors:

- Red Hat Enterprise Linux 5.2 running native on an Intel Xeon® X7460-based (2.66 GHz) server
- Red Hat Enterprise Linux 5.2 running as guest on Red Hat Enterprise Linux 5.2 server on an Intel Xeon X7460-based (2.66 GHz) server

KEY FINDING

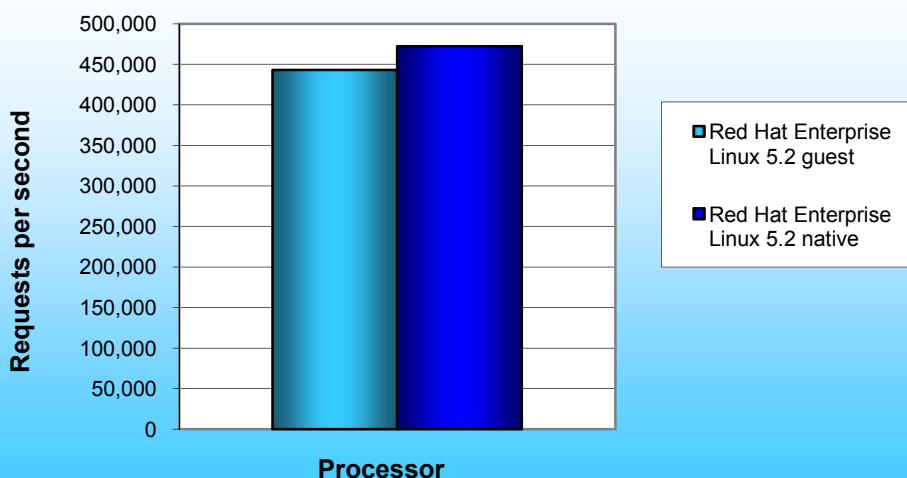

- Red Hat Enterprise Linux 5.2 guest on an Intel Xeon X7460-based server achieved 93.7 percent of the performance of running native on Red Hat Enterprise Linux 5.2 (see Figure 1).

In this section, we present the best results for each server. For complete details of the performance of each Java Virtual Machine (JVM) by warehouse for each server, see the Test results section.

Figure 1 shows the SPECjbb2005 results, in bops (business operations per second), of the test servers. Each result is the median peak score of three runs of the benchmark. See the Test results section for the scores from all three runs. A higher SPECjbb2005 score indicates the server is able to handle more Java requests and thus deliver greater throughput. We configured the benchmark to utilize all of the cores of the Intel Xeon 7460 processor running both native and as a guest on Red Hat Enterprise Linux 5.2.

The Red Hat Enterprise Linux 5.2 guest on Red Hat Enterprise Linux 5.2 configuration achieved a score of 443,088 bops, which is 93.7 percent of the performance of running native on Red Hat Enterprise Linux 5.2. That configuration achieved a score of 472,625 bops.

SPECjbb2005 results

Workload

SPECjbb2005 is an industry-standard benchmark created by the Standard Performance Evaluation Corp. (SPEC) to measure a server's Java performance. (Note: SPEC and the SPECjbb2005 are trademarks of the Standard Performance Evaluation Corporation.) SPEC modeled SPECjbb2005 on the three-tier client/server architecture, with the middle layer as the primary focus. According to SPEC, "Random input

Figure 1: Peak performance of the servers with the SPECjbb2005 workload. Higher numbers are better.

selection represents the first (user) tier. SPECjbb2005 fully implements the middle tier business logic. The third tier is represented by tables of objects, implemented by Java Collections, rather than a separate database.” (www.spec.org/jbb2005/docs/UserGuide.html).

SPECjbb2005 utilizes multiple special data groups and multiple threads as it runs. Each data unit is a “warehouse,” a roughly 25MB collection of data objects. Each thread represents an active user posting transaction requests within a warehouse. The benchmark run begins with one warehouse and then increases the number of warehouses; its goal is to saturate the server’s processor capacity. As the number of warehouses increases, so does the number of threads. The benchmark’s results portray the server’s throughput in business operations per second or SPECjbb2005 bops. A higher number of SPECjbb2005 bops is better. (For more information on SPECjbb2005, go to www.spec.org.)

Test results

Figure 2 shows the median SPECjbb2005 results for both servers. In each test, we ran four JVMs at the same time, a common practice on servers with many processors. To compute the overall score for the system, SPECjbb2005 sums the scores of all the JVMs and gives a final score along with the average bops/JVM. SPECjbb2005 computes the score of each JVM by taking the average of the results during mixes when the server is running at peak performance. (In SPEC’s terms, these results are from “compliant” runs, which means we can disclose them publicly though we are not posting them on the SPEC Web site with all the files SPEC requires. We do present here all the data necessary to reproduce these results.)

	Red Hat Enterprise Linux 5.2 server: Intel Xeon X7460-based server	Red Hat Enterprise Linux 5.2 guest on Red Hat Enterprise Linux 5.2 server: Intel Xeon X7460-based server

Figure 4: SPECjbb2005 results for the Red Hat Enterprise Linux 5.2 guest on Red Hat Enterprise Linux 5.2 server: Intel Xeon X7460-based server. Higher numbers are better.

Test methodology

Red Hat configured and provided the test system.

We began by installing a fresh copy of Red Hat Enterprise Linux on the test system. For the Red Hat Enterprise Linux 5.2 native installation, we installed only the Software Development package, and disabled the firewall and SELinux. We used the same installation method for the Red Hat Enterprise Linux 5.2 guest installation, but installed Virtualization on the native installation for this configuration. We made no additional changes to the default installation options.

With the following exceptions, we used the default BIOS settings on each server: enabled AHCI, Intel Virtualization Technology, and High Bandwidth. In addition, we disabled both HW prefetcher and Adjacent Cache prefetcher.

SPECjbb2005 configuration

We used SPECjbb2005 version 1.07, dated March 15, 2006. We followed SPEC's run rules. (For more information about SPECjbb2005 and its run rules, see www.spec.org/jbb2005/docs/RunRules.html.) We installed SPECjbb2005 by copying the contents of the SPECjbb2005 CD to the directory C:\SPECjbb2005v1.07 on the server's hard disk.

SPECjbb2005 requires a Java Virtual Machine on the system under test. We used the BEA JRockit SE Runtime Environment 1.6.0_03 (build P27.5.0-5_o_CR371811_CR374296-100684-1.6.0_03-20080702-1650-linux-x86_64, compiled mode) JVM for this testing and left the default installation settings.

After installation, as per the run rules, we edited the SPECjbb_config.props file in the root SPECjbb2005 directory to include disclosure information about the server and our license information. SPECjbb2005 uses this file when generating the results output for each run. We also modified the SPECjbb.props file to change the number of JVM instances to 4. This change allows a server to run 4 JVM instances during testing.

We created a shell script, which we placed in the root SPECjbb2005 directory, to issue the Java run command to launch the benchmark. During testing, we used the command prompt window to run this batch file. Figure 5 shows the contents of the shell script we used on the Red Hat Enterprise Linux 5.2 native configuration.

In the shell script we set the Java options that control the performance of the JVM.

- `-Xms3500m` sets the minimum heap size. We set the minimum and maximum heap sizes to be the same, so the heap size would stay a constant 3500MB.
- `-Xns2500m` sets the JVM nursery size.
- `-Xmx3500m` sets the maximum heap size.
- `-XXaggressive` basically tells the JVM to perform at maximum speed.
- `-XXlargepages` tells the JVM to use large pages.
- `-Xgc:genpar` sets generational parallel garbage collection.
- `-XXthroughputCompaction` adjusts the compaction ratio dynamically based on live data in the heap.
- `-XXlazyUnlocking` affects when the JVM releases locks.
- `-XXtlasize` sets the thread-local area size the JVM uses.
- `-XXcallprofiling` allows the use of call profiling for code optimizations.

Figure 5: The text of the shell script we used to execute the SPECjbb2005 benchmark on Red Hat Enterprise Linux 5.2 native configuration.

We used the same shell script on the Red Hat Enterprise Linux 5.2 guest running on Red Hat Enterprise Linux 5.2 server, but modified a few of the options. We made the following changes: 3400 instead of 3500 for the `-Xms` and `-Xmx` option. The reason for these changes is the size of available memory differs between the two configurations because the guest OS is virtualized and has a higher memory overhead.

Appendix A – Test system configuration information

This appendix provides detailed configuration information about each of the test server systems, which we list in alphabetical order.

Figure 6: Detailed system configuration information for the two test servers.

* The size of the memory modules differs between the two configurations because a guest OS is virtualized. This means that the native OS is running at the same time as the guest OS. The native OS needs available memory, thus reducing the amount available for the guest OS.

Appendix B – SPECjbb2005 output

This appendix provides the SPECjbb2005 output files from the median run for both servers.
